Genetic Transformation Of Plants Molecular

Whilst genetic transformation of plants is commonly viewed as a means of bringing about plant improvement, it has not so readily been recognised as a tool for analysing the function of plant genes. This book is unusual in that it focuses on the genetic transformation of a range of plants using a number of different methods.

Molecular genetic studies with Arabidopsis have already identified many gene functions in plants. Molecular genetics relies on sexual crosses mutagenesis and genetic transformation to identify genes. Arabidopsis transformation relies on Agrobacterium-mediated gene insertion except that there is no tissue culture step.

Genetic Selection, Genetic Transformation

Plant transformation refers to the transfer and incorporation of engineered genes or plasmids into the plant genome. It is not only an essential biotechnological approach for in-depth research of plant growth, but also a promising tool for modern agriculture, specifically for the introduction and selection of desired crop traits.

can serve as a boon for improvement of perennials such as fruit crops wherein crop improvement is often difficult because of their long juvenile period, heterozygosity, and reproductive barriers (cross- and self-incompatibility). Moreover, since most of the adapted cultivars lack only one or a few characters, transferring the gene of interest can enhance the efficiency of the cultivar and preserve its original identity.

Genetic transformation provides direct access to a vast pool of useful genes not previously accessible to plant breeders. The first transgenic plants with *Bacillus thuringiensis* (Bt) genes were produced in 1987, while most of the insect-resistant transgenic plants have been developed by using Bt endotoxin gene [72] .

In molecular biology and genetics, transformation is the genetic alteration of a cell resulting from the direct uptake and incorporation of exogenous genetic material from its surroundings through the cell membrane. For transformation to take place, the recipient bacterium must be in a state of competence, which might occur in nature as a time-limited response to environmental conditions such as starvation and cell density, and

Being natural plant genetic engineers, in the 1980s, *A. tumefaciens* started to be exploited in biotechnology for plant genetic transformation . Modified Ti plasmids, which lacked T-DNA genes related to the syndrome (disarmed), though retaining the entire vir (virulence) region, were used for the introduction and integration of foreign DNA in the plant cells and subsequent regeneration of transgenic plants.

Speciation can be easier in many plants due to unique genetic abilities, such as being well adapted to polyploidy. Plants are unique in that they are able to produce energy-dense carbohydrates via photosynthesis, a process which is achieved by use of chloroplasts. Chloroplasts, like the superficially similar mitochondria, possess their own DNA.

Genetic Transformation | IntechOpen

In molecular biology, transformation is the genetic alteration of a cell by the direct uptake and expression of DNA from its surroundings. Transformation occurs naturally in some species of bacteria, and can also be done artificially. Bacteria that are capable of being transformed, whether naturally or artificially, are called competent.
